**Abstract**

The goal of achieving carbon neutrality is now a shared objective for humanity, with countries worldwide setting specific greenhouse gas (GHG) reduction targets by 2030. While initial concerns about global warming focused on fossil fuel use post-industrial revolution, perceptions shifted in the 2010s, highlighting the livestock industry as a significant contributor. However, a survey showed that the energy sector accounts for 71.2%, while agriculture contributes to only 11.9% of global GHG emissions, with only 7% of agricultural GHG coming from livestock. According to data from the Food and Agriculture Organization, the livestock sector accounts for 13.5% of the total GHG emissions. In Korea, GHG emissions from the agricultural sector are reported to be 2.9%, of which the livestock sector accounts for 1.3%. These findings underscore that the livestock industry is not the primary GHG emitter, emphasizing the need for intensive reduction efforts across high-emission industries like energy. Hence, setting accurate, data-based reduction targets and guidelines is crucial for effective GHG emissions mitigation.

29 Greenhouse gases, Environment

## 30 **Introduction**

31 The argument that the livestock industry is a major contributor to the  
32 climate crisis stems from the Food and Agriculture Organization of the  
33 United Nations' (FAO) 2006 report, "Livestock's Long Shadow." It  
34 stated that greenhouse gas (GHG) emissions from livestock supply  
35 chains accounts for 18% of the total emissions and this industry emits  
36 more GHGs than the world's entire transportation system (Steinfeld,  
37 2006). However, this is an unfair comparison. GHG emissions from the  
38 livestock industry comprises those produced during the course of the  
39 entire supply chain—from growing feed crops, manufacturing and  
40 transporting feed, raising livestock, transporting livestock, slaughtering,  
41 processing, and selling to disposal of feed. Meanwhile, GHG emissions  
42 from the transportation sector include those from all vehicles, such as  
43 cars, ships, planes, and trains (Kim and Na, 2008). To make a fair  
44 comparison, the GHG emissions of each mode of transport should  
45 include the sum of those produced during manufacturing, operation, and  
46 disposal, as well as production, processing, and distribution of petroleum  
47 as fuel.

48 In terms of direct emissions alone, transportation accounts for 16.9%  
49 and livestock accounts for 7%, while in Korea, transportation accounts  
50 for 13.5%, and livestock accounts for 1.3%. Global GHG emissions from

51 the livestock industry are less than half of that of the transportation sector,  
52 and in Korea, GHG emissions from the livestock sector is only 1/10 of  
53 those from the transportation sector (Fig. 1) (Jo, 2021).

54 Nevertheless, in recent years, claims that the livestock industry is a  
55 major contributor of GHGs have gained momentum, leading to the  
56 perception that livestock production is one of the causes of the climate  
57 crisis. In fact, vegetarian meals are being introduced in Korean  
58 educational institutions, which are part of the public sector. Additionally,  
59 local and national governments are introducing various programs to  
60 encourage vegetarianism or replace livestock products with other foods  
61 (Jo, 2021).

62 Therefore, in this review, we investigated the actual situation  
63 regarding GHG emissions from the agricultural and livestock sectors to  
64 resolve the misunderstanding related to excessive GHG emissions from  
65 livestock production and provide data to encourage a joint effort by all  
66 industries to reduce emissions by formulating appropriate policies.

67

## 68 **Status of GHG emission in Korea**

69 In 2010, the energy, industrial processes, and agriculture sectors  
70 accounted for 68.0%, 7.0%, and 11.0% of emission of the major GHG  
71 gases, namely carbon dioxide (CO<sub>2</sub>), methane (CH<sub>4</sub>), and nitrous oxide

72 (N<sub>2</sub>O), respectively, and other sources accounted for 14.0% of the  
73 emissions (IPCC, 2014; <http://www.ipcc.ch>). According to the National  
74 Greenhouse Gas Inventory Report of the Korean Ministry of  
75 Environment, Korea's total GHG emissions in 2018 were 727.6 million  
76 tons of CO<sub>2</sub> equivalent, i.e., an increase of approximately 149% from  
77 292.2 million tons in 1990. Nearly 87% (approximately 632 million tons)  
78 of the total emissions in 2018 were from the energy sector; nearly 7.8%  
79 (approximately 57 million tons), from industrial processes; nearly 2.9%  
80 (approximately 21 million tons), from agriculture; and nearly 2.3%  
81 (approximately 17 million tons), from waste (Kang, 2021). Although  
82 South Korea's GHG emissions have been gradually increasing, the  
83 agricultural sector's contribution to national GHG emissions decreased  
84 by more than 3% in 2017 when compared with that in 1990 owing to the  
85 continuous decline in rice cultivation since 1990, decline in livestock  
86 production after the foot-and-mouth disease outbreak in 2010, and GHG-  
87 absorbing ability of forests and grasslands (Kang, 2021). Total GHG and  
88 CO<sub>2</sub> emissions decrease and increase in an N-shaped relationship  
89 depending on Korea's economic growth, while CH<sub>4</sub> and N<sub>2</sub>O emissions  
90 increase and decrease in an inverted U-shaped relationship. Additionally,  
91 the agricultural sector in Korea has different impacts depending on the  
92 source of GHG emissions. CH<sub>4</sub> and N<sub>2</sub>O, in particular, rise with

93 increased agricultural production in Korea, indicating the need for policy  
94 or technology development in this sector. In order to support the 2030  
95 GHG Reduction Roadmap, promotion of GHG- reduction technologies  
96 or policies can help the country achieve the associated targets. However,  
97 expansion of GHG reduction policies that do consider agricultural  
98 production and food security at the national level can predict reduction  
99 in production in the agricultural sector and damage to related industries  
100 (Kang, 2021; Lee et al., 2019). Therefore, the introduction of detailed  
101 GHG reduction policies and technologies that consider the industrial  
102 characteristics of the agricultural sector and the relationships between  
103 GHG emission sources is necessary (Kang, 2021).

104

### 105 **GHG emission in agriculture sector**

106 The agricultural sector is both an emitter and absorber of GHGs (Kim  
107 and Lee, 2009). The consumption ratios of light and livestock sectors to  
108 the total energy consumption of the agricultural sector is 53.5% and  
109 46.5%, respectively, and their ratios to the total energy consumption  
110 volume is 55.3% and 44.7%, respectively, with light consistently higher  
111 than that of the livestock sector (Kim and Lee, 2009). Considering  
112 domestic GHG emissions, the agricultural sector is regarded as both an  
113 emitter and absorber of GHGs. Hence, the economic impact of reducing

114 GHGs in the agricultural sector can be expected to be quite large (Kim  
115 and Lee, 2009). The major GHGs generated in the agricultural sector are  
116 CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O. According to data from the US Environmental  
117 Protection Agency, CO<sub>2</sub> accounts for approximately 70% of GHG  
118 emissions. CH<sub>4</sub> accounts for 23% of GHG emissions in the atmosphere,  
119 although its proportion is gradually increasing. While rice paddies  
120 constitute the largest portion of Korea's agricultural area and are  
121 beneficial by contributing to flood control, climate moderation, and air  
122 purification (Ki et al., 2012), they are also a major source of GHG  
123 emissions (mainly, CH<sub>4</sub>). This is because organic materials, such as  
124 fertilizers and compost, injected during rice cultivation are decomposed  
125 by bacteria in oxygen-poor freshwater, producing CH<sub>4</sub> gas. However,  
126 most people are not aware that GHGs are produced in rice fields. A report  
127 by the United Nations Intergovernmental Panel on Climate Change  
128 (IPCC) also pointed out that since the 20th century, rice farming has been  
129 a major contributor of CH<sub>4</sub> emissions, and they need to be controlled  
130 (Kim and Na, 2008; Park, 2021). Moreover, Reiner Wassmann, a climate  
131 change expert at the International Rice Research Institute, highlighted  
132 the contribution of rice cultivation to the GHG emissions of Asian  
133 countries, and further stated that rice cultivation is not the main  
134 contributor, but must be given attention in efforts to reduce GHG

135 emissions in Asian countries (Wassmann et al., 2019). While CO<sub>2</sub> has a  
136 greater impact on global warming, CH<sub>4</sub> is known to be 21 times more  
137 potent than CO<sub>2</sub> as a GHG (Kim and Na, 2008; Park, 2021).

138 According to data from the Korean Ministry of Environment, light  
139 cropping and livestock farming are sources of GHGs in the agricultural  
140 sector (Government Republic of Korea, 2020). From 1990 to 2010, light  
141 cropping showed a decreasing trend and livestock farming, an increasing  
142 trend, which then stagnated. In 2017, the amount of light cropping and  
143 livestock farming emissions were 11.8 million tons CO<sub>2</sub> equivalent and  
144 8.6 million tons CO<sub>2</sub> equivalent, respectively (Table 1) (Jang and Pyeon,  
145 2020). Decreased GHG emissions from light farming since 1990 was due  
146 to the continual reduction of emissions caused by rice cultivation, which  
147 is the main source of emissions, owing to the decrease in paddy  
148 cultivation area. The slowing down of increased emissions from the  
149 livestock sector since 2010 was due to the outbreak of diseases, such as  
150 foot-and-mouth disease, while the slight rise in 2017 (0.1 million tons  
151 CO<sub>2</sub> equivalent, which indicated a 1.4% increase from the previous year)  
152 was the result of escalation of the number of cattle raised (Jang and  
153 Pyeon, 2020). In 1990, the share of GHG emissions from rice cultivation  
154 was 10.5%, which was almost twice of that from livestock farming, i.e.,  
155 5.6%. In 2017, the share of GHG emissions from rice cultivation was 6%

156 and that from livestock farming was 8.6% (Ministry of Environment of  
157 Korea, 2020). In other words, all agricultural sectors contribute to GHG  
158 emissions, and carbon emissions can be reduced only if efforts for this  
159 are concentrated both in the livestock farming and crop agriculture  
160 sectors.

161

### 162 **GHG emission in livestock sector**

163 In the "Research on Development of Carbon-Saving Livestock  
164 Product Distribution Technology in Response to Global Warming"  
165 report of the Korea Rural Development Administration, carbon  
166 emissions generated during the production and distribution of major  
167 livestock (cattle and pigs) were calculated. The distribution of 1 kg beef  
168 was found to emit 2.1 g, 24.3 g, and 308 g of CO<sub>2</sub> during 10 days of aging,  
169 26 days of storage, and 3 days of display, respectively (Cho et al., 2015).  
170 This is roughly three times more than the CO<sub>2</sub> emissions associated with  
171 curing, storing, and displaying 1 kg pork of the same weight. This is  
172 likely because beef takes about three times longer to mature and store  
173 than does pork. The carbon emissions during production, slaughtering,  
174 processing, and distribution of 1 kg raw Korean beef were 16.55 kg,  
175 17.58 kg, 27.41 kg, and 27.75 kg, respectively. These values were about  
176 7 to 8 times higher in the production and slaughtering stages and about

177 2.5 times higher in the processing and distribution stages than those for  
178 pork in these stages (Cho et al., 2015).

179 According to a report regarding carbon emissions generated during the  
180 distribution of domestic and imported beef, 1 kg Hanwoo beef was found  
181 to emit 27.75 kg carbon during the production and distribution stages and  
182 1 kg US beef, 92 kg carbon during the distribution stage compared with  
183 the production stage, indicating that US beef generated about three times  
184 more carbon emissions during distribution than did Hanwoo beef (Cho  
185 et al., 2015).

186 A previous case study based on beef production in Canada showed  
187 that in terms of the percentage of GHGs emitted during cattle raising,  
188 intestinal fermentation accounted for 63.12% (CH<sub>4</sub>) emission, while  
189 18.73% (N<sub>2</sub>O) and 13.38% (CH<sub>4</sub>) emission came from manure.  
190 Meanwhile, in the energy sector, automobiles accounted for 3.39% (CO<sub>2</sub>)  
191 GHG emission, and the soil where feed crops are grown, 1.39% (N<sub>2</sub>O)  
192 GHG emission (Fig. 2) (Chen et al., 2020)

193 In the meat industry, production of 1 kg beef resulted in CO<sub>2</sub> emissions  
194 of 39 kg on the farm, 2 kg during animal feed production, and 2 kg during  
195 processing. These values for pork were 2 kg on the farm, 3 kg during  
196 animal feed production, and 1 kg during processing. During chicken  
197 meat production, these values were 1 kg on the farm, 2 kg during animal

198 feed production, and 1 kg during processing (Fig. 3) (Roper, 2020).

199 According to an Our World in Data report, GHG emissions due to the  
200 production of 1 kg food were 16 kg CO<sub>2</sub> because of land use change and  
201 39 kg from the farm in the case of beef production and approximately 12  
202 kg GHG during the production of shrimp, which was more than that  
203 emitted during the production of 1 kg pork or chicken. Rice, which is the  
204 staple food in Korea, was also found to produce approximately 3.6 kg  
205 GHG per kg of rice (Fig. 4) (Poore and Nemecek, 2018).

206 Based on data from the United States Department of Agriculture  
207 (USDA) and others, per capita CO<sub>2</sub> emissions calculated using the food-  
208 consumption method showed that meat-eaters emitted 3.3 kg GHGs per  
209 day, while the average person emitted 2.5 kg GHGs per day; this value  
210 is close to that related to persons who do not consume beef (1.9 kg) and  
211 vegetarians (1.7 kg) (Poore and Nemecek, 2018). Vegans emitted 1.5 kg  
212 GHGs, which means that among all people, meat-eaters contribute to  
213 approximately 50% of the GHG emissions. Considering GHGs emitted  
214 during food production, 60 kg GHGs were required to produce 1 kg beef  
215 and 21 kg GHGs, to produce 1 kg cheese. Considering plants, 19 kg  
216 GHGs were required to produce 1 kg chocolate and 17 kg GHGs, to  
217 produce 1 kg coffee (Fig. 5) (Arnold et al., 2013).

218 The Princeton University released a report stating that the percentages

219 of GHGs emitted during the generation of livestock products were  
220 approximately 39% due to fermentation in the animal's intestines;  
221 approximately 45% from land use, chemical fertilizers, manure/compost,  
222 feed production, transportation, and feed processing; and 10% from  
223 manure storage. Post-slaughter processing and transportation accounted  
224 for approximately 6% of the total GHG emissions (Fig. 6) (Grossi et al.,  
225 2019; Gerber et al., 2013). The GHG emission rate associated with the  
226 production of 1 kg poultry meat in a poultry farm was 1.26 kg from feed  
227 production, 0.55 kg from transportation, 0.28 kg N<sub>2</sub>O from manure, and  
228 0.26 kg from farm energy (Dunkley and Dunkley, 2013). GHG emissions  
229 associated with the consumption of 1 kg eggs was 0.06 kg from  
230 processing, 0.35 kg from transportation, 0.13 kg from farm energy, and  
231 0.53 kg from feed production (Vetter et al., 2018).

232

### 233 **Conclusion**

234 Korea is the 11th largest emitter of GHGs in the world, and this  
235 number is very close to its economic position. Hence, there is  
236 international pressure to reduce GHGs. Korea has announced a goal of  
237 reducing GHG emissions by 40% from the 2018 levels by 2030 to  
238 become carbon neutral by 2050.

239 Our review shows that the agricultural sector accounts for only 2.9%  
240 of GHG emissions and the livestock sector, for a very low 1.3%.  
241 However, the energy sector accounts for more than 80% of the total GHG  
242 emissions. These data show similar trends not only in Korea but also in  
243 other countries worldwide. It is also important to note that rice  
244 cultivation and other arable agriculture contribute more significantly to  
245 GHG emissions than does livestock farming. Therefore, to achieve  
246 carbon neutrality, efforts are needed in the agricultural sector and  
247 livestock industry, but the greatest effort would be required to convert  
248 the highest percentage of energy to renewable energy. Livestock was  
249 recognized as a major contributor of GHG emissions after the publication  
250 of the FAO's "Livestock's Long Shadow" report, which claimed that  
251 emissions from livestock are greater than those from the transportation  
252 sector and are a major contributor of land and water degradation  
253 (Steinfeld, 2006). However, the data we have researched and presented  
254 shows that while livestock is a source of GHG emissions, it is by no  
255 means the most significant one. Therefore, livestock must not be  
256 recklessly claimed as a major source of GHG emission. The  
257 implementation of carbon emission reduction policies centered around  
258 sectors associated with high GHG emissions based on accurate

259 information obtained by collecting objective data is important to achieve  
260 carbon neutrality in 2050.

### Status of GHG emission in the world

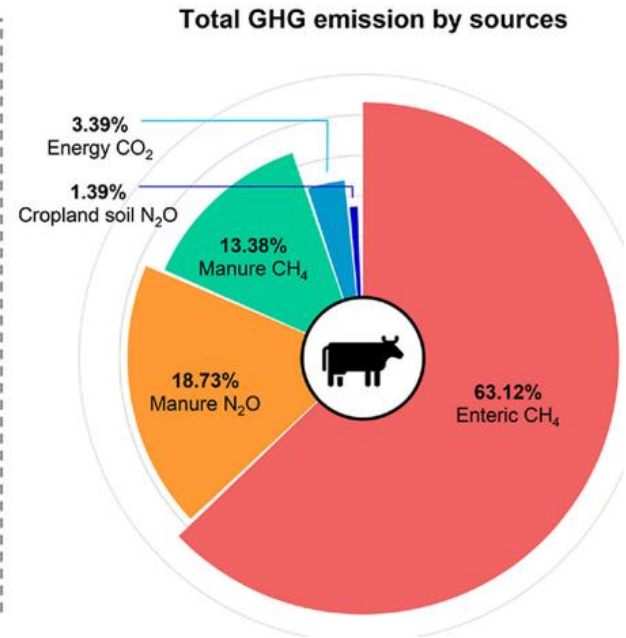

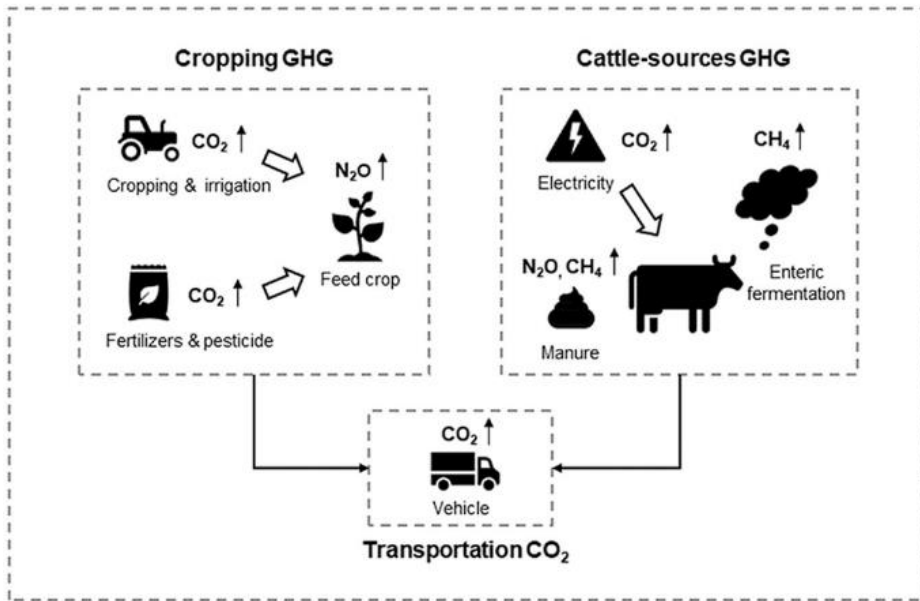

### Status of GHG emission in Korea

350

351 **Fig. 1.** Graphical representation of the status of greenhouse gas (GHG) emission in world and Korea (Jo, 2021). MTC;  
352 million tones carbon dioxide equivalent, ETC.; et cetera.

353

354 **Fig. 2.** Percentage of greenhouse gas emissions by sources as a result of raising cattle (Chen et al., 2020).

355

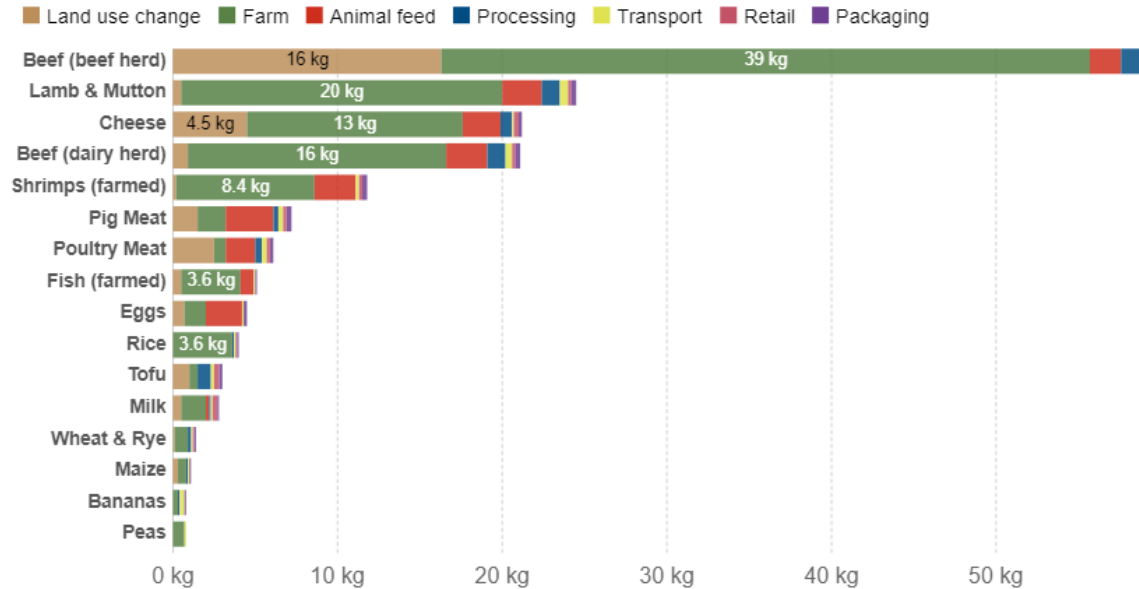

356 **Fig. 3.** Greenhouse gas emissions due to meat production by species (Roper, 2020).

## Food: greenhouse gas emissions across the supply chain

Our World  
in Data

Greenhouse gas emissions are measured in kilograms of carbon dioxide equivalents (kgCO<sub>2</sub>eq) per kilogram of food. This means non-CO<sub>2</sub> greenhouse gases are included and weighted by their relative warming impact.

Source: Poore, J., & Nemecek, T. (2018). Reducing food's environmental impacts through producers and consumers. *Science*.  
 Note: Data represents the global average greenhouse gas emissions of food products based on a large meta-analysis of food production covering 38,700 commercially viable farms in 119 countries.

357

358 **Fig. 4.** Greenhouse gas emissions across the supply chain (Poore and Namecek, 2018).

## Foodprints by Diet Type: t CO<sub>2</sub>e/person

Note: All estimates based on average food production emissions for the US. Footprints include emissions from supply chain losses, consumer waste and consumption. Each of the four example diets is based on 2,600 kcal of food consumed per day, which in the US equates to around 3,900 kcal of supplied food.

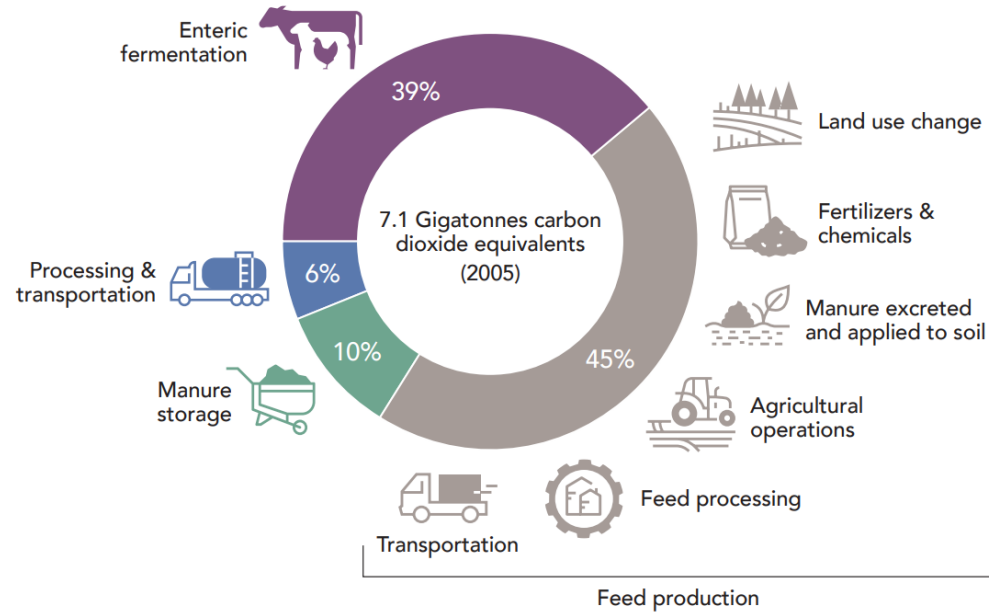

Sources: ERS/USDA, various LCA and EIO-LCA data

359

360 **Fig. 5.** Per capita greenhouse gas emissions by food consumption methods (Arnold et al., 2013). t CO<sub>2</sub>e/person; metric tons

361 of carbon dioxide equivalent per person.

362

363 **Fig. 6.** Percentage of greenhouse gas emissions by sources resulting from raising of livestock (modified from source:

364 Livestock and climate change: impact of livestock on climate and mitigation strategies) (Grossi et al., 2019).

365 **Table 1.** Trends in greenhouse gas emissions in the agricultural sector (1990–2017) (Jang and Pyeon, 2020)

366

		Unit: million tons CO <sub>2</sub> eq					
		1990	2000	2010	2015	2016	2017
Whole country		292.2 (100%)	503.1 (100%)	657.6 (100%)	692.3 (100%)	692.6 (100%)	709.1 (100%)
Agriculture (livestock, farming) Subtotal		21.0 (7.2%)	21.2 (4.2%)	21.7 (3.3%)	20.8 (3.0%)	20.5 (3.0%)	20.4 (2.9%)
Gas	Methane gas (CH <sub>4</sub> )	14.3	13.2	12.9	12.0	11.9	11.7
	Nitrogen peroxide (N <sub>2</sub> O)	6.7	8.0	8.9	8.9	8.6	8.7
Seedling	Subtotal	15.4 (5.3%)	14.2 (2.8%)	13.0 (2.0%)	12.1 (1.7%)	12.0 (1.7%)	11.8 (1.7%)
	Rice cultivation	10.5	8.7	7.3	6.3	6.2	6.0
	Farmland soil	4.9	5.6	5.7	5.8	5.8	5.8
	Crop residue incineration	0.033	0.029	0.024	0.021	0.020	0.019
Animal husbandry	Subtotal (Enteric fermentation, fecal urine treatment)	5.6 (1.9%)	7.0 (1.4%)	8.7 (1.3%)	8.7 (1.3%)	8.5 (1.3%)	8.6 (1.2%)
